TITLE: Methods of Intensification of De-watering of Flotation Concentrate. (Puti intensifikatsii protsessa obezvozhivaniya flotokontsentrata)

PERIODICAL: Koks i Khimiya, 1957, No.6, pp. 6 - 9 (USSR)

ABSTRACT: Possibilities of increasing the efficiency of vacuum filters for flotation concentrates are discussed. Operational data of vacuum filters in foreign countries are given for comparison (Table 1). According to data of Kal'miusskoy TsOF the cost of filtering of 1 ton of concentrates is 1.26 Rouble, of which 0.73 Rouble is the cost of electric power, thus a decrease in power consumption should be the main source of possible economy. The costs of beneficiation and de-watering of concentrates on foreign works are given in Table 2. Intensification of the filtration process can be obtained by increasing the density and temperature of the pulp, the influence of which is shown in Figs. 1 and 2 and Table 3. The other method of improving the de-watering process is the use of hydrophobic surface-active substances. The influence of aerozole and tergitol additions on the moisture content of filter cake is shown in Figs. 3 and 4, respectively. It is Card 1/2 concluded that unsatisfactory operation of filters is mainly

Methods of intensification of De-watering of Flotation Concentrate. 68-6-2/19
due to irregularities in their operation, in the first place
due to wrong blow-off practice (separation of filter cake from
the filter). A considerable increase in the output and a
decrease in power consumption can be obtained by introducing
flash blow-off. Further improvements can be obtained by
increasing the density and temperature of the pulp as well as
by application of surface-active substances. There are 3 tables,
4 figures and 9 references, 3 of which are Slavic.

TITLE: Physico-chemical Methods of Reducing Moisture Content of
Coal Blends for Coking (Fiziko-khimicheskiye metody
snizheniya vlazhnosti koksovoy shikhty)

PERIODICAL: Koks i Khimiya, 1957, no.12, pp. 12 - 16 (USSR)

ABSTRACT: An investigation of the influence of surface active substances on de-watering of coal fines (filtration or centrifuging) was investigated. Size distribution of coal slurries investigated are given in Table 2. Experimental technique was to filter slurries under constant conditions and to determine the moisture content in the filter cakes. Experimental results are given in Tables 4 and 5, respectively. Capillary heights for coals of various sizes with and without two different surface-active substances were determined - Table 6. It is concluded that the method has possibilities of practical application as additions of some surface-active substances decreased considerably the moisture content of the filter cakes and increased the velocity of filtering. There are 6 tables and 3 references, 2 of which are Slavic.

TITLE: Study of the reactions of the free methyl radical with organosilicon compounds

SOURCE: Vysokomolekulyarnyye soyedineniya, v. 7, no. 6, 1965, 1085-1091

TOPIC TAGS: organosilicon compound, organic chemistry, methyl radical, siloxane compound, polymerization

ABSTRACT: The reactions of the free methyl radical with organosilicon compounds containing different organic groups (methyl, phenyl, vinyl, allyl, and trifluoropropyl) at the silicon atom were investigated. The relative activity of these groups in the reaction of the methyl radical addition and the hydrogen atom abstraction is discussed by means of formulas. Cyclic compounds of the type $(R_1R_2SiO)_4$ were used. The source of free radical was acetyl peroxide decomposing during heating in solution according to $(CH_3COO)_2 \rightarrow 2CH_3 + 2CO_2$. The quantitative evaluation of the two reactions was carried out on the basis of methane yield

Card 1/3

L 60140-63
ACCESSION NR: AP5016512

determination during the decomposition of acetyl peroxide in a $[(\text{CH}_3)_2\text{SiO}]_4$ solution. The ratio of the velocity constants (k_2/k_1) for both reactions is given by an equation. Tabulated data are given for the reaction of the methyl radical with aromatic silicon compounds at 95°C. It was found that in siloxane compounds the probability of the addition of methyl radical to the phenyl group at the silicon atom is 5 times as great as the probability of the hydrogen abstraction from CH_3 . The acceptor capability of the phenyl group with respect to the methyl radical in siloxanes is 16 times that of benzene. Tabulated data given for the reaction of the methyl radical with vinyl siloxanes and vinyl silanes at 80°C show that vinyl siloxanes are polymerized to a polymer with a molecular weight of 2500. The methane yield increased gradually with decreasing vinyl siloxane concentration. In the reaction of the methyl radical with allyl silanes and allyl siloxanes, the probability of the addition of the methyl radical to the allyl double bond is 39-43 times as great as that of the hydrogen abstraction from the methyl group of the compounds investigated, and only 4 times as great as the probability of the hydrogen removal from the corresponding compounds. α -methylene groups play an important role in the hydrogen abstraction. In vinyl silanes and vinyl siloxanes, the k_2/k_1 ratio is 86 and 140, respectively.

Cord 2/3

L 60140-65

ACCESSION NR: AP5016512

2

This shows a higher reactivity of the vinyl groups in the reaction with free radicals as compared with allyl radicals. The reactivity of the double bonds of vinyl and allyl types in siloxanes is much higher than in silanes. In the reaction of the methyl radical with vinyl siloxanes in the presence of organic fluorosilicon compounds, the methane yield is the same as by using octamethylcyclotetrasiloxane as a solvent. The experimental procedure is described, and the experimental apparatus is explained and illustrated. Orig. art. has: 3 figures, 4 tables, and 7 formulas.

TITLE: Electro-pulse machining of parts of pneumatic and hydraulic equipment

PERIODICAL: Stanki i instrument, no. 3, 1962, 21-23

TEXT: General information on the process of electro-pulse machining of parts of pneumatic and hydraulic equipment is given and special tools for producing connecting ducts in parts of hydraulic pumps, distributor valves, pressure regulators, etc., without cutting through the surface, are described. The special L-shaped tool shown in photographs consists of a holder for fitting the machine spindle, and a traverse for holding a tool-electrode of required size and contour. Re-placeable collars are used on the traverse for setting the electrode to the required duct dimensions and preventing electric contact between the traverse and the workpiece metal. Collars are of any material insusceptible to the effect of the work fluid. The process is more productive than electro-spark erosion, the electrode wear is low, and large-sized ducts of any contour can be produced. The tool can be used in electro-pulse or any broaching machines, and not only ducts of circular contour can be made. One electro-pulse machine described has a special

Card 1/2

Electro-pulse machining

MГИ -2 (MGI-2) generator. Red copper, ENIMS graphite compositions and **T15K6** (T15K6) hard alloy were tried as electrode material, and **ЭЭГ** (EEG) graphite electrodes were found to be the best for the electro-pulse process, whilst hard alloy electrodes proved good in the electro-spark process. The wear of EEG electrodes did not exceed 0.4 % of removed metal volume in producing 8 x 20 mm ducts in silumin. The tool setting for required duct dimensions is described. There are 5 figures.

TITLE: Tool feed direction during electric impulse machining of profiled surfaces

SOURCE: Stanki i instrument, no. 5, 1965, 34-35

TOPIC S: electric impulse machining, spark machining, profile machining

ABSTRACT. The optimum direction of the tool during the finishing cut in electric impulse machining is evaluated to provide the minimum cutting time (minimum material removal). The minimum depth of the finishing cut when the tool is not perpendicular to the point being machined is given by

$$\Delta_s = \{(H_1 + T_1) - (H_2 + T_2)\} : \cos \alpha,$$

where α = angle between tool feed direction and normal to surface, H_1 and T_1 , H_2 and T_2 - depth of irregularities and thickness of affected surface layer for rough and final cuts respectively. The total tool displacement necessary between the rough and final cuts is

Cord 1/2

$$B = \Delta_s + (b_1 - b_2) : \cos \alpha,$$

L 57064-65

ACCESSION NR: AP5013786

where δ_1 and δ_2 - electrode clearance during rough and finish cuts respectively. Since α can change from 0-90° for a single profile, the tool should be placed at some angle to the profile to minimize the finishing depth of cut. A procedure for finding this optimum angle is developed for a profile made of arcs of circles. In this case the profile is calculated with respect to one coordinate system (all radii of curvature are drawn in an x-y coordinate system), the two points which result in the maximum deviation of the normal to the surface from the vertical on both sides of the vertical are determined, and the optimum tool angle then becomes

$$\alpha_{opt} = \frac{\delta_1 + \delta_2}{2}$$

where A and D are the points where the normal deviates most from the vertical. The maximum α encountered during the cut will then be

$$\alpha_{max} = \frac{\delta_D - \delta_A}{2}$$

and this will provide minimum material removal necessary during the finishing cut with a fixed tool angle. The procedure is demonstrated on an example. Orig. art. has: 2 figures and 8 formulas.

TITLE: Finding the Reynolds number in convective heat exchange relationships 21

SOURCE: Moscow. Institut inzhenerov zhelezno-dorozhnogo transporta. Trudy, no. 189, 1965. Issledovaniye teploobmena v teploenergeticheskikh ustancvakh i v ustancvakh dlya polucheniya poluprovodnikovykh materialov (Investigation of heat exchange in thermal power units and in equipment for producing semiconductor materials), 103-109

TOPIC TAGS: Reynolds number, heat exchange, thermodynamic analysis

ABSTRACT: This article examines certain peculiarities which take place during various approaches to the determination of the Reynolds number. The numerical values of the Reynolds number are calculated from the formulas:

$$Re' = \frac{vd}{\nu} ; \quad (1)$$

$$Re'' = \frac{Gd}{\mu f} , \quad (2)$$

Card 1/2

L 62552-65

where w is the rate of motion of the fluid in m/sec; d is the decisive dimension in meters; ν is the kinematic viscosity of the fluid in m^2/sec ; μ is the dynamic viscosity of the fluid in $N \cdot sec/m^2$; G is the mass flow of the fluid in kg/sec ; f is the cross section of the channel in m^2 . In formula (1) the calculation is done by linear velocity, and in formula (2)--by mass flow. These two expressions are not identical in all cases. If the physical parameters refer to a temperature which is different from the mean temperature of the flow, then the values for Re calculated by (1) and (2) will differ. Formulas are derived relating these two expressions and examples are given to illustrate the use of these formulas. It is recommended that formula (1) should be used for forced airflow since there is a smaller scatter of points in this case when the temperature simplex is very different from unity. When the physical parameters relate to a temperature which differs from the flow temperature, the values of Re and invariant relationships differ when finding Re according to linear velocity and according to mass flow. There is less scatter of the experimental points when Re is calculated according to linear velocity. Orig. art. has: 3 figures and 12 formulas.

TITLE: On the Free Flexural Vibration Frequencies of Arches with Elastically Restrained Ends. (O sobstvennykh chastotakh izgibnykh kolebaniy arok s uprugo zashchelennymi pyatami)

PERIODICAL: Nauch. tr. Leningr. inzh.-stroit. in-ta, 1956, Nr 23, pp 28-42

ABSTRACT: The free vibrational frequencies of circular arches are calculated approximately, with due consideration given to the elasticity in the constraint of their ends, which, meanwhile, are assumed to remain undisplaced. An exact transcendental equation of the free vibrational frequencies is adduced for arches constrained by two terminal hinges, and its unsuitability for practical purposes is established.

The solution of the given problem is accomplished by the Bubnov-Galerkin method. In the approximating beam functions utilized there-in the linear arguments are replaced by angular ones. The Author asserts that the application of such functions enables one to determine the free vibrational frequency of arches of any form.

Card 1/2

124-11-13111
On the Free Flexural Vibration Frequencies of Arches with Elastically Restrained
Ends. (Continued)

Practically convenient, approximate formulas are obtained for the case of antisymmetrical (i. e., with two semi-waves) and symmetrical (i. e., with three semi-waves) vibrations of arches.

A boundary case is investigated, when the elastic constraint becomes either a hinge or a rigid clamping.

PURPOSE: This collection of articles is intended for research physicists and engineers. It can also be used by instructors and students at universities.

CONTENTS: The articles of this collection contain the results of 19 studies in transport problems of the Institute of Physics and Mathematics and Theoretical Physics of the S.M. Kirov Kazakh University. The articles are arranged in two groups. Group one contains 16 articles concerning the research activity of the Teplofizicheskaya laboratoriya pri kafedre obnaruzheniya fiziki (Heat Physics Laboratory of General Physics) in the investigation of transport processes of transport processes of matter, impulse and energy. Group two contains three articles reporting on studies of the Department of General Physics on problems of the theory of relativity. Article one of the collection is an introduction and review the problems of transport processes and gives a fairly detailed bibliography of contributions or members of Physics department of Kazakh State University. No personalities are mentioned. References accompany each article.

TITLE: Measuring ionization function² of metal atoms by electron impact

SOURCE: Zhurnal prikladnoy mekhaniki i tekhnicheskoy fiziki, no. 2, 1965, 94-96

TOPIC TAGS: electron impact, ionization, electron beam, atomic beam, ionisation cross section/ U1 2 amplifier, ENO 1(S 1 4) oscilloscope, MA 20 balance

ABSTRACT: A method is described for measuring the absolute ionization cross section of low vapor pressure metal atoms by electron impact. The apparatus used for this experiment is shown in Fig. 1 on the Enclosure where 1- neutral atom source, 2- atomic beam chopper, 3- electron beam, 4- neutral atom collector, 5- ion collector, 6- thermopile, 7- cooled collector for neutral atoms, 8- LM-2. The metal used was lead. An electrostatic selector was employed to make the electron beam monoenergetic. This was done successfully to within 0.35 ev electron energy. The ion current was measured by an electrometric amplifier U1-2 with an error of less than 8%. The ionization measurements were carried out from the threshold level up to 150 ev with a maximum ionization cross section of

Card 1/3

L 54008-65

ACCESSION NR: AP5013379

3

$8 \times 10^{-16} \text{ cm}^2$ at 55 ev. The ionization cross section was determined from the expression $Q = I_b m t b v / I_N$ where b is the atom beam width at the point of intersection with the electron beam, t is the evaporation time and m is the atomic mass. A special effort was made to measure the neutral atom concentration accurately, condensing them on a collector cooled by liquid nitrogen. "The authors express their deep gratitude to V. L. Granovskiy (deceased) for his help and advice. Thanks are also given to Z. I. Sinitina and A. A. Mal'kov for preparing the apparatus." Orig. art. has: 3 figures and 1 equation.

AUTHORS: Beylina, L. V., Kislyakov, I. P.

TITLE: Investigating the wettability and impregnability of titanium and zirconium nitride briquets with molten cobalt and nickel

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy, Tsvetnaya metallurgiya, no. 3, 1962, 129 - 134

TEXT: To complete data on the preparation and properties of nitride-base alloys, the authors studied the preparation of Ti and Zr-nitride powders and the identification of their composition; the pressing and sintering of porous briquets; the wettability of nitrides with molten nickel and cobalt and the impregnability of porous briquets with these materials. The nitrides were obtained from standard grade Ti and Zr metals or oxides. Nitriding of the metals was carried out in two stages with slow temperature rise to 1,100 and 1,150°C. Nitriding of oxides was performed in 3 stages at 1,600°C. The composition and parameters of the crystal lattice of nitrides and the nitride grain size were determined. Briquets were pressed in a steel mold from Ti and Zr-nitride powders, mixed with a 5% rubber solution in benzine. The briquets were sintered in a vacuum furnace

with a molybdenum heater, at 500 - 600°C for 45 minutes and at 1,400 - 1,450°C for 60 minutes. Impregnability and wettability of the briquets with molten nickel and cobalt was tested in the same furnace. The Co powder contained in %: 99.5 Co; 0.22 Ni; 0.10 O; 0.01 C; 0.06 Fe; 0.04 Si; 0.07 aq. The Ni powder was composed (in %) of: 99.56 Ni; 0.07 Co; 0.10 O; 0.01 C; 0.056 Fe; 0.04 Si; 0.016 C; 0.14 aq. Average values of wetting angles were determined. The tests yielded the following results: In wetting Ti-nitride with molten Co and Ni the wetting angles are in both cases below 90°. The possibility of saturating porous briquets, pressed from Ti-nitride powder, with molten metals, depends upon the purity and the granulometric composition of the nitride powder. Ti-nitride obtained by nitriding high-purity Ti metal can be sufficiently well impregnated with molten Co and Ni. Ti-nitride obtained by nitriding Ti-oxide in the presence of carbon (black) is wetted by the metal but not impregnated. This is explained by contamination with free carbon and its fine-grained nature. Zr-nitride obtained by nitriding Zr-metal powder is wetted with molten Co and Ni but not impregnated, this is probably due to the aforementioned causes and to the presence of residual oxygen, preserved on account of incomplete nitriding. It is assumed that the pseudo-binary Ti nitride - Ni and Ti nitride - Co sections show an eutectic nature,

WETTING OF WC AND TiC BY MOLTEN Cu AND Cu-Ni ALLOYS (USSR)

Kislyakov, I. P., L. V. Beylina, and A. N. Kuzin. Izvestiya vyschikh uchebnykh zavedeniy. Tsvetnaya metallurgiya, no. 1, 1963, 117-120.

S/149/63/000/001/005/008

The Moscow Institute of Fine Chemical Technology has studied the wetting of solid WC and TiC by molten Cu, Cu-Ni alloys (with up to 30% Ni), Ni, and Co at 1080 to 1250°C in a pure Ar atmosphere. It was found that WC is readily wet by both Cu and Cu-Ni alloys. The contact angle θ in these systems is less than 90°, even at temperatures only 10-20°C above the melting point of the lowest-melting component. The θ decreases with increasing exposure time at a constant temperature or with increasing temperature. The temperature of complete wetting ($\theta = 0$) was found to be 1220-1250°C for Cu, and 1200-1220°C for the Cu-Ni alloys. The Cu-Ni alloys wet WC at a lower temperature, and more rapidly at the same temperature, than Cu; the higher the Ni content, the more rapid the wetting. No wetting of TiC by

Card 1/2

AID Nr. 978-1 28 May

WETTING OF WC AND TiC [Cont'd]

S/149/63/000/001/005/008

Cu or Cu-Ni alloys was observed at temperatures up to 1250°C and exposure time up to 2 hrs. It is believed, however, that a higher purity of TiC or increased exposure time would facilitate wetting. Complete wetting of TiC with Ni or Co takes place at temperatures 20 and 30°C higher than the melting temperature of Ni and Co, respectively. Melting at lower than the melting temperatures of pure Ni and Co, observed at the Ni-TiC and Co-TiC interfaces, is associated with the eutectic nature of the pseudobinary TiC-Ni and TiC-Co systems. The qualitative effect of the exposure time and temperature on the wetting of TiC by Ni and Co is similar to that in the wetting of WC by Cu and Cu-Ni alloys.
